# CONTENTS

# QUANTUM-REGIONS INTERCONNECTED BY LOCAL DESCRIPTIONS

The QUILD (*Quantum-regions Interconnected by Local Descriptions*) program [*1-2* (page 53)] has been developed by M. Swart and F. M. Bickelhaupt for enabling calculations through multi-level approaches, in which different computational treatments are used for different regions of the system under study. M. Swart ( http://iqc.udg.es/~marcel (http://iqc.udg.es/~marcel/)) F. M. Bickelhaupt ( http://www.few.vu.nl/~bickel (http://www.few.vu.nl/~bickel/)) User support ( support@scm.com) This manual did not change much since the ADF 2009.01 version.

# TWO

# WHAT'S NEW IN THE 2018 VERSION

An interface to the AMS driver has been added, allowing QUILD to use all AMS engines to be used with QUILD. The interfaces to the old standalone programs (e.g. DFTB) have been removed, since these do not exist anymore in the 2018 release. See *AMS driver interface example* (page 48).

# WHAT'S NEW IN THE 2017 VERSION

## 3.1 Anti-ferromagnetic coupling

Automated optimization for anti-ferromagnetically coupled dinuclear transition-metal systems (with SpinFlip approach in ADF). See Ref. [*48* (page 56)].

## 3.2 Upscaling low frequencies in Gibbs free energy

Upscaling of low frequencies for correct entropy in Gibbs free energy (controlled by FREQ_CUTOFF keyword, in cm-1) (both scaled and unscaled Gibbs free energy is given).

## 3.3 Bug fix

Bugfix for combination of delocalized coordinates and frozen coordinates.

# WHAT'S NEW IN THE 2009.01 VERSION

## 4.1 GUI-support

AMSinput has been adapted to provide full support for the multi-level setup in QUILD.

## 4.2 Symmetry within QUILD

QUILD tries to use symmetry as much as possible, but only for the geometry; as such, more symmetries are possible than within ADF (for the orbitals). For instance, it enables the use of S4 symmetry for the geometry and C2 for the orbitals. Moreover, with the use of the *SYMROT* (page 31) subblock one can rotate coordinates from e.g. D5h to C2v for ferrocene. Therefore, this allows the separation of geometric and orbital symmetry.

## 4.3 More QM programs

Apart from ADF, NewMM and ORCA (for which an interface was already present), the new version includes interfaces to DFTB and MOPAC, and a *GENERIC* (page 35) one to accommodate a generic QM program maintained by the user itself. The user-program only has to be able to transform the QUILD-generated coordinates into an energy/gradient etc. and return data in the format as specified (a simple text file). A working example for HONDO is available.

## 4.4 Frequency calculations for QM, MM and multi-level QM/QM and QM/MM schemes

Fully operational calculation of the Hessian in case of multi-level schemes, where for each description either an analytical or numerical setup can be chosen. This can be applied automatically for either QM calculations, MM calculations, or multi-level QM/MM or QM/QM calculations (including spin-contamination corrections). A full summary of the important thermodynamic properties (enthalpy at 0K and 298K, entropy, Gibbs free energy) is reported in the output, for instance:

## 4.5 Spin-contamination correction per region

The spin-contamination ($S^2$) correction has been folded into the multi-level setup, which means the user can do a $S^2$-correction for only one region. This option is now available for energy, gradients (optimizations, TSs) and Hessians (vibrational frequencies, numerical and analytical). See the section on *spin-contamination correction per region* (page 37) for more details.

## 4.6 Improved TransitionState (TS) search

Simplification of initial Hessian generation, which makes it generally available for any elements of the Periodic Table. This should further enhance Transition State searches, which for Baker's set of 25 TSs results in complete localization of all TSs within 343 cycles (i.e. 14 cycles per TS).

## 4.7 Simplified and more detailed output

The QUILD output has been drastically reduced (e.g. without the repetitive output of the Create runs in ADF), and at the same time more detail is given. At each optimization step, the progress of the optimization is reported:

```
Geometry Optimization Progress
-------------------------------------------------------
Item                  Value        Crit    Convgd
-------------------------------------------------------
Gradient Max       0.052637     0.000100      NO

```

# 4.8 Improved generation of primitive coordinates

A new subroutine is used for generating the primitive coordinates, which should lead to less and more important coordinates (icreate 7).

## 4.9 Frozen coordinates versus constraints

A number of Cartesian coordinates can be kept frozen (with the *FROZEN* (page 31) subblock), without the need to put additional constraints that may be sometimes awkward to put. This can be for instance be the case when the user wants to treat the active site of an enzyme and freeze certain atoms (e.g. the C? atoms) to mimic the effect of the protein environment.

## 4.10 Numerical gradients per region

The numerical gradients that can be used within QUILD are now completely generalized, and can be specified per region. For instance, if one wants to use the numerical gradient of a hybrid-metagga functional (such as e.g. mPBE0KCIS) for a small part of the total system, and the analytical gradient of a GGA for the rest, it is simple and straightforward to achieve this:

```
QUILD

# BASIC PHILOSOPHY

The QUILD program [*1-2* (page 53)] has been developed for enabling calculations through multi-level approaches, in which different computational treatments are used for different regions of the system under study. The benefit of our multi-level approach is not only that it can be used to make the calculations cheaper and therefore feasible, but also that the best method for any type of interaction can be used as we need for DNA (*vide infra*). For describing DNA, we use one DFT functional for treating the complete system, and another for $\pi$-stacking between the DNA bases. This is achieved by making the definition of the regions flexible, i.e. there is no need to have a layered structure as in the ONIOM approach. An arbitrary splitting of the total system into different regions is permitted with, therefore, possibly overlapping regions; this resembles a quilt, hence the name of the program.

The different treatments currently possible are based on either quantum mechanics (QM) or force field molecular mechanics (MM). The MM part is provided through the NEWMM program that is included within the ADF [*3-4* (page 53)] program package since the 2006.01 version. Density Functional Theory [*5-7* (page 53)] is provided by the ADF program, while an interface for the ORCA program [*ORCA* (page 56)] is available for inclusion of Hartree-Fock (RHF/UHF), Möller-Plesset (MP2) or semi-empirical (e.g. AM1, PM3) calculations. New in the 2009.01 version is the inclusion of DFTB (for Density Functional Tight Binding), Mopac (semi-empirical, e.g. PM6), and a generic (QM) program that allows the user to apply his/her own program. In all these cases, the other programs are used as black-box programs to deliver the energy and gradient, i.e., QUILD writes the inputfiles, runs the black-box programs, collect the data, makes new coordinates, and repeats this process until the geometry is optimized.

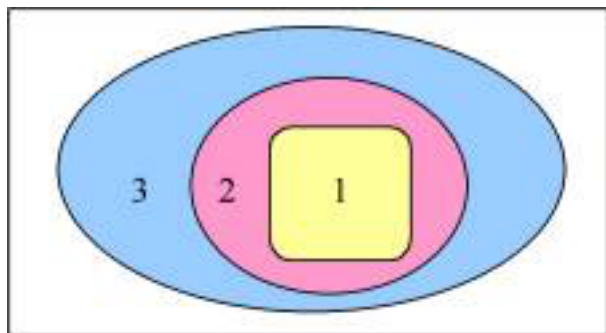

The application of multi-level (QM/QM or QM/MM) approaches within computational chemistry studies is ever more often used, since it permits to use a highly accurate method for the most important region while treating the interactions with the surrounding regions at a lower, yet sufficiently accurate method. The QM/MM setup (see Figure), where only the region of interest (region 1, in yellow) is treated with quantum chemistry methods while the interactions with and within the surrounding regions is described with classical molecular mechanics force fields, is the computationally most economical multi-level approach. Its accuracy and applicability depend largely on the accuracy and availability of force field parameters for the system under study. Specialized force fields are available for certain classes of chemical systems, such as the AMBER95 force field [*8* (page 53)] for proteins and nucleic acids, which is included within the ADF program package using the NEWMM program. *However, the treatment of large biochemical systems containing thousands of atoms with QUILD is not to be advised due to the making of the adapted delocalized coordinates, involving a diagonalization step that is not feasible for systems with more than ca. 700 atoms (estimated). Treating large biochemical systems are best performed by the QM/MM scheme [9-11 (page 53)] in ADF.*

Because of the computational efficiency, the availability of basis sets for the whole Periodic System, and the generally accurate results, Density Functional Theory (DFT) has become the method of choice for the majority of recent computational chemistry studies and can these days almost routinely be used for relatively large system sizes of up to hundred of atoms (the largest system used with ADF in single-point calculations contained ca. 1200 atoms; the largest system used within geometry optimizations contained ca. 700 atoms) [*12-20* (page 53)]. However, one must always remain cautious with the choice of DFT functional and/or basis set, and make sure that the particular functional is able to give a correct description for the interactions that are important for the system under study. For instance, the performance of functionals that include the recent OPTX exchange functional [*21* (page 54)] is superior to those containing Becke88 exchange [*22* (page 54)], for instance for the accuracy of geometries [*23-24* (page 54)], spin state splittings [*25-26* (page 54)], reaction barriers [*23,27-28* (page 54)], or zero-point vibrational energies [*23* (page 54)]. As the improvements can be linked directly to the specific formulation of the OPTX functional [*26,29* (page 54)] and its resulting improved performance for atomic exchange energies [*21* (page 54)], one would naively think that inclusion of the OPTX functional would always lead to improved performance. Unfortunately, this is not the case for weakly bound systems, as shown recently for hydrogen-bonding [*30* (page 55)] and $\pi$-stacking [*31* (page 55)] in DNA. Moreover, a functional that performs well for hydrogen-bonding interactions (BP86 [*22,32* (page 54)]) [*30,33-37* (page 55)] does not necessarily give equally good results for $\pi$-stacking [*31* (page 55)]. As a result, at present there does not seem to be a DFT functional that is equally accurate for hydrogen-bonding, $\pi$-stacking and intramolecular interactions. Therefore, for a study on the structure of DNA duplexes, the multi-level QM/QM approach [*2* (page 53)] is needed with one DFT functional for the description of hydrogen-bonding interactions, and another for the description of $\pi$-stacking, which can be exploited within the QUILD scheme.

In the Figure above, a schematic structure of DNA is presented with the bases (regions 1 to 4, in orange), and sugars and phosphate backbone (region 5, in cyan). Since BP86 works well for intramolecular interactions and hydrogen-bonding interactions, but not for $\pi$-stacking, BP86 is used for the whole system, and for the $\pi$-stacking its interactions are replaced by LDA.

# MULTI-LEVEL ENERGY EXPRESSION

Similar to the ONIOM approach [*38-39* (page 55)] the total energy within the multi-level approach is obtained by combining the different energies, for instance, for the interactions in a protein depicted schematically below, with the active site (region 1, in yellow), the rest of the protein (region 2, in pink) and solvent (region 3, in blue).

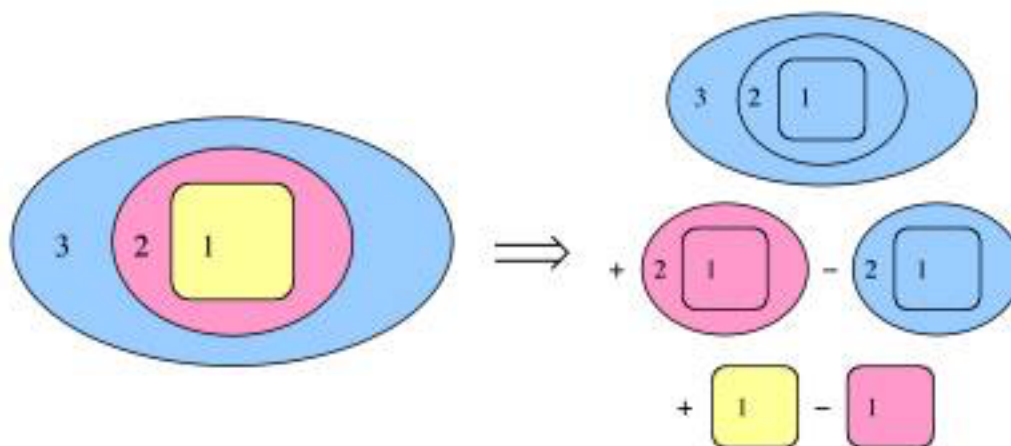

Suppose we want to treat the active site using a GGA functional in a large basis set, the rest of the protein by LDA in a small basis, and the solvent at MM level. The energy expression is then obtained by a sequence of 5 jobs:

$$E = E_{MM}(1,2,3) + E_{LDA}(1,2) - E_{MM}(1,2) + E_{GGA}(1) - E_{LDA}(1)$$

First, the total system is described at the MM level (top-right), then the MM description for regions 1 and 2 is replaced by LDA (middle-right), and finally the LDA description for region 1 is replaced by the GGA description (bottom-right). This splitting up of the total system into different jobs is fully automated, the user only has to assign the different regions and give descriptions for the QM and MM methods to be used.
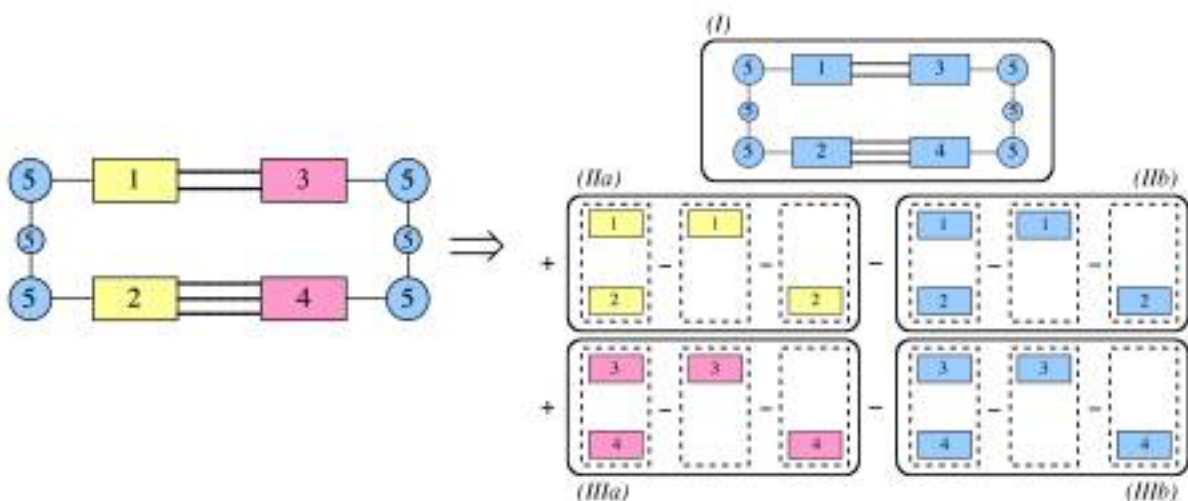

A second example of using a multi-level approach is posed by the application to DNA. In this case we do not want to replace all interactions within one region, but merely the *interaction* between two different regions. This is again achieved by a sequence of jobs, as indicated in the figure above on the right hand side. First, we have a BP86 job for the whole system (top, in blue). Second, we add the LDA interaction energy for the left-side stacked basepair in a series of three jobs (middle, in yellow) and remove the corresponding BP86 interaction energy (middle, in blue). Third, we add the LDA interaction energy (bottom, in pink) and remove the corresponding BP86 interaction energy (bottom, in blue) for the right-side stacked basepair.

The corresponding input for the second example would be schematically:

```
QUILD

    INTXN region 3 region 4      description 3 for description 2
  SUBEND

END
```

Next, we provide a line-by-line explanation of the above input:

```
QUILD
```

All input relevant for performing the QUILD job must be specified within a QUILD block. QUILD takes care of the remaining input that is needed in runs of ADF or other programs that are invoked (in a "black-box" manner) by QUILD. Exceptions are, for example, GEOMETRY, GEOVAR, etc., which are specified according to the ADF input syntax. Thus, detailed input parameters for the various programs that QUILD communicates with can be passed through to these programs via the QUILD input block (within DESCRIPTION subblocks, see below). Therefore, any option that is available in ADF (ZORA, COSMO, LDA, GGA, MGGA, HYBRIDS) or in the other programs (NEWMM, ORCA, DFTB, MOPAC, GENERIC) is also available in QUILD.

```
NR_REGIONS 5
```

The number of regions is set to five. The definition of the atoms that belong to each region is given in the REGION subblocks below:

```
REGION 1
  17-30
SUBEND
REGION 2
  77-91
SUBEND
REGION 3
  47-60
SUBEND
REGION 4
  111-122
SUBEND
REGION 5
  1-16 31-46 61-76 92-110 123-125
SUBEND
```

In the above example, atoms 17 to 30 make up region 1 (an equivalent input would be to specify each atom number individually, i.e.: "17 18 19 20 21 22 23 24 25 26 27 28 29 30"), atoms 77 to 91 region 2, atoms 47 to 60 region 3, atoms 111 to 122 region 4, and the remaining atoms region 5. *It is not necessary to define all regions explicitly: the first job (with the description as defined by the* TOTAL *line in the* INTERACTIONS* subblock) includes all atoms automatically. Only those regions which are explicitly used within the*INTERACTIONS* subblock need to be defined, i.e. in this case the definition of region 5 is not actually used.* Note that the atom numbers are obtained by counting consecutively the atoms in the ATOMS block on input.

```
DESCRIPTION 1

  BASIS
    type TZ2P
    core SMALL
  END
SUBEND
DESCRIPTION 2
  XC
    GGA Becke-Perdew
  END
  BASIS
    type TZ2P
    core SMALL
  END
SUBEND
DESCRIPTION 3
  BASIS
    type TZ2P
    core SMALL
  END
SUBEND
```

Given here are the different descriptions that are needed for the BP86 and LDA treatments of the different regions. Note that there are two different descriptions using BP86, one (DESCRIPTION 1) for the complete system that has total charge -2, and a second one (DESCRIPTION 2) for the interaction between two stacked bases. For non-ADF (i.e. NEWMM, ORCA, DFTB, MOPAC, or GENERIC) jobs, on the first line of the corresponding DESCRIPTION subblock it should say so, as given in the example below for description 4 (HF/STO-3G with ORCA):

```
DESCRIPTION 4 ORCA   ! Options are ADF, DFTB, NEWMM, MOPAC, ORCA, GENERIC
  %coords
    mult 2
    charge -1
  end
  %method method hf
  end
  %basis basis sto_3g
  end
SUBEND
```

Note that in case of geometry optimizations where one of the jobs uses ORCA, the run-type (keyword runtyp) should be set to "gradient" in order that a "job*.engrad" file is written (by ORCA) that contains the ORCA energy and gradient. The QUILD program will automatically add this runtyp keyword to the corresponding input block. If the ORCA job deals with either an unrestricted job, or with a non-zero charge, it is best to put these data in the %coords block as shown above.

Together with the general input (apart from ATOMS, GEOMETRY, etc. blocks that are automatically generated by

the QUILD program) the contents of these DESCRIPTION subblocks will constitute the "black-box" inputfile for the different programs. If there are differences in charge (*vide supra*), the charges of the total system and the regions should be given in these DESCRIPTION subblocks. Also when either the region is Unrestricted and the total system not (or vice versa), the description of being unrestricted (or not) should be given in the DESCRIPTION subblocks. Note that the general input contents is pasted only into input files for programs within the ADF program package, for external programs such as ORCA **only the automatically generated atomic coordinates part and the part given in the DESCRIPTION subblock is put into the input file for the ORCA job.**

```
INTERACTIONS
  TOTAL      description 1
  INTXN region 1 region 2       description 3 for description 2
  INTXN region 3 region 4       description 3 for description 2
SUBEND
```

This is the subblock that determines how the multi-level job is setup. The total system will be treated by description 1, i.e. BP86 for all atoms. Then in the second line, the BP86 interaction between regions 1 and 2 is replaced by the corresponding LDA interaction. In the last line, the BP86 interaction between regions 3 and 4 is replaced by the LDA interaction. In total there are therefore 5 ADF(by jobs per geometry cycle. When the ADF program package is setup to run in parallel, and this is taken care of properly in the $AMSBIN/start script, then also within QUILD this is used. At present no attempt has been made yet to prepare the interface for the parallel version of ORCA, the user is responsible for installing the ORCA program.

# ADDREMOVE METHOD FOR CAPPING ATOMS

Whenever the definition of a region splits through a covalent bond (or better put, whenever QUILD notices that there are dangling bonds within a certain job), it will automatically add capping atoms to satisfy the valence of the boundary atoms (see for instance Figure below). For the moment, the program automatically adds hydrogen as capping atoms, which in the future may be changed to include other elements as well, if needed.

The capping atoms are added according to the AddRemove methodology [40 (page 55)], in which the capping atoms follow the position of the real atoms in the total system. I.e. the capping atoms are positioned along the vector of the dangling covalent bond, and at a distance that corresponds to the sum of the covalent radii of the capping atom and the atom to which the capping atom is attached. Because the capping atoms are added to the active site for both the high- and low-level QM calculation, with a presumably similar effect in both cases, the interactions of the capping atoms with the true active site atoms are in good approximation canceled out (the total effect is removed) between the lower- and higher-level QM calculations. Within the AddRemove model, the energy and gradients are treated in similar fashion (unlike other models that project the gradients of the "artificial" capping atoms onto the gradients of the "real" atoms). The AddRemove model was previously [40 (page 55)] shown to perform well for geometries around the boundary between the QM and MM region in QM/MM calculations.

In summary, the AddRemove model [40 (page 55)] has several advantages: it is simple, the energy and gradients (and Hessian) are treated in similar fashion (unlike other models that for instance project the gradients of the capping atoms onto the gradients of the real atoms). Furthermore, the capping atoms follow the real atoms, at a predefined distance, and therefore no artificial degrees of freedom are added by including the capping atoms. In a strict sense, one could even argue that the replacement of the interactions of the capping atoms is performed consistently with the choices made for the multi-level approach.

There is only one case where the use of the AddRemove model within the QUILD program is not straightforward, and that is posed by MM regions with dangling bonds (see Figure above, bottom right). The description of the MM region depends explicitly on a force field, that in turn needs for each atom in the MM region an atomtype that should be supplied by the

user on input, together with all connection tables for all atoms. As the QUILD program automatically adds capping atoms ($H_{cap}$ in the Figure above), the DESCRIPTION subblock for the NEWMM description of the capped region (Figure above, bottom right) should include the atomtype and connections for the automatically added capping (hydrogen) atoms.

The program checks for each job in a multi-level scheme, if they have atoms with dangling bonds. It does this by going over all regions that are included in that particular job; the order in which the regions are checked depends on how the regions are given on input (!). For instance, in the following line, region 2 is checked first and then region 1 as second:

```
REPLACE region 2 region 1    description 3 for description 2
```

For checking the dangling bonds in each region, the program goes sequentially through all atoms and checks if they belong to that particular region; if so, and if the atom has a dangling bond (as the $C_\alpha$ atom has in the Figure above) a capping atom is added, which is positioned along this dangling bond.

# IMPROVED GEOMETRY OPTIMIZATION

One of the strong points of the QUILD program [*1-2* (page 53)] apart from its flexible setup of the multi-level approach, is its enhanced geometry optimization capabilities. These result in part from the use of adapted delocalized coordinates [*41* (page 55)], a modification of the original delocalized coordinates setup [*42* (page 55)], that enables the use on weak coordinates as well. Further enhancements are obtained through the use of regulated GDIIS [*43-44* (page 55)], Restricted Second Order model (trust region) [*45-46* (page 56)], and a model Hessian [*41* (page 55)]. The latter includes the generation of a model Hessian for transition state searches by preparing the initial Hessian with the correct curvature and number of negative eigenvalues, which moreover correspond to the reaction coordinates (TSRC) for the transition state under study. The user has to specify on input what the relevant TSRC coordinates are, which will not only be used for the generation of the initial Hessian, but also to select the appropriate Hessian eigenvector when there are more (or less) than 1 negative Hessian eigenvalues.

The details of setting up the delocalized coordinates, its adaptation to facilitate the use on weak and strong coordinates, and their characteristics can be found in refs. [*41* (page 55)] and [*2* (page 53)]. Here we briefly mention the performance of the QUILD program for the Baker test set (a set with 30 organic molecules) and a test set with 18 weakly-bound molecules [*2* (page 53)]. For the Baker set, we need 167 iterations to fully converge all molecules to a gradient of 3.0 $10^{-4}$ a.u. at RHF/STO-3G (results obtained using the interface to ORCA), and 164 at PW91/TZ2P. For comparison, the old-style optimizer in ADF using Cartesians needed 222 iterations. For the weakly-bound set, we need 175 iterations to fully optimize the molecules to a gradient of 1.0 $10^{-5}$ a.u. at PW91/TZ2P. Again for comparison, the old-style optimizer in ADF using Cartesians needed 748 iterations.

As an example, below is the relevant input for performing a transition state search for the bimolecular nucleophilic substitution reaction of fluoride on methyl chloride (see figure):

The QUILD program will scan the input for the existence of a Geometry block (that indicates that QUILD should do an optimization), and will scan the Geometry block for the presence of the TransitionState keyword. If it is found, it will set the number of negative Hessian eigenvalues that are needed (nrnegneed) to 1, otherwise it will remain 0.

The QUILD block should in this case contain a TSRC subblock where the coordinates involved in the transition state are given. In the example above, there are two TSRC coordinates, the C-Cl and the C-F bond, as indicated by the atom numbers. For the construction of the initial Hessian, a negative force constant is assigned to these coordinates. For instance in the outputfile, first the definition is given for the primitive coordinates as they are constructed by the QUILD program (with the TSRC coordinates shown below in blue):

```
Number of MM coordinates (valence,intramol,intermol) :   32 (   32,    0,    0)
-------------------------------------------------------------------------------
                          valence coordinates
-------------------------------------------------------------------------------
     1  bnd              2     1     0     0     1           1.02076
     2  bnd              3     1     0     0     1           1.02076
     3  bnd              4     1     0     0     1           1.02076
     4  bnd              5     1     0     0     1           0.50000
     5  bnd              6     1     0     0     1           0.50000
     6  ang              3     1     2     0     2           0.90892
     7  ang              4     1     2     0     2           0.90892
etc.
```

Further down in the output, the force constants for the different MM coordinates are shown (with the ones for the TSRC coordinates given in blue):

```
Force Constants used:

 bnd     1   0.40831      bnd     2   0.40831      bnd     3   0.40831      bnd     4↵
↪  -0.03252
 bnd     5  -0.02804      ang     6   0.20839      ang     7   0.20839      ang     8↵
↪   0.20839
etc.
```

which are also coupled with each other:

```
Off-diagonal TSRC Hessian-element :        5     4  -0.04271           -0.02804  -
↪0.03252
```

And finally, the contributions of the TSRC coordinates to the Hessian eigenvalues is reported:

```
Weight TSRC-coord      1     4    1.00000 Flindh      0.50000
Weight TSRC-coord      2     5    1.00000 Flindh      0.50000

Contributions of TSRC coordinates to negative Hessian eigenvalue     1 is    0.99996
Contribution from primitive      5    0.49998    Bnd     F     6     C     1

Additionally, the QUILD optimizer allows to constrain bonds, angles or dihedrals during the optimization, in which it uses the method by Baker [*47* (page 56)]. This method has the nice feature that the constraints do not have to be met in the initial geometry, but are enforced through the use of Lagrangian multipliers. The ability of adding constraints has been extended to perform a LinearTransit, i.e. a series of constrained optimizations, that can be used to scan a potential energy surface as function of e.g. a bond. For the $S_N$ 2 reaction shown above, the relevant input to do a LinearTransit would be:

```
QUILD
  nrlt 11
  CONSTR
    dist 1 6 2.5 1.5
  SUBEND
END
```

This means that the C-F distance is reduced (while constrained) in 11 steps, starting from 2.5 Å and going to 1.5 Å, in steps of 0.1 Å. All other coordinates are free to optimize in this example, however a combination of more than one constrained coordinates is possible; either by including them also as LT coordinate, or simply as constraint.

# SPECIAL CASES

Because the QUILD program serves as a wrapper around the ADF, NEWMM and ORCA programs, it has additional capabilities that may not be present within these programs themselves. A numerical evaluation of the energy gradients in QUILD enables the use of geometry optimization techniques for any methodology within either of these programs, also for those for which only the energy expression is known or implemented (for instance meta-GGA or hybrid functionals, or excited states within ADF) and for which geometry optimizations are otherwise out of reach (see for example ref. [27 (page 54)] for geometry optimizations with meta-GGA functionals, and ref. [2 (page 53)] for optimizations of excited state and spin-orbit geometries). It should be noted that because of the numerical evaluation of the gradients, requiring 6N+1 energy calculations per geometry step (with N the number of atoms), these calculations do require a significantly larger CPU-time. Note that the capabilities of ADF will change during the years, and some of the remarks above may not be completely true anymore. Spin-orbit coupled optimizations in ADF are possible in ADF2007. In ADF2009 some hybrid, meta-GGA and meta-hybrid functionals can be used during the SCF and for optimizations (analytical gradient).

A second additional capability is the possibility to perform a geometry optimization for the pure spin states in systems that suffer from spin contamination. The spin contamination is simply projected out, not only for the energy but also for the gradient (and Hessian), by performing two consecutive jobs, one for the contaminated spin state, a second with the multiplicity increased (that is mixed in into the contaminated job). For instance, the following example gives an example input:

```
QUILD

  INTERACTIONS
    TOTAL   description 1
    S2CORR description 2
  SUBEND

  DESCRIPTION 1
    CHARGE 0.0 1.0
    Unrestricted
  SUBEND
  DESCRIPTION 2
    CHARGE 0.0 3.0
    Unrestricted
  SUBEND

END
```

See ref. [25 (page 54)] for an example of using this setup on a spin-contaminated system.

# HOW TO CALL THE PROGRAM

The QUILD program is available in the general 2009.01 release of ADF, and should be called in similar fashion as ADF, e.g.

```
#! /bin/sh

$AMSBIN/quild << eor
! Normal ADF input, maybe extended with a QUILD inputblock (see below)
eor
```

The user is responsible for the installation of external programs such as ORCA, MOPAC or a GENERIC program. For the use of ORCA, the user should make sure that the following works:

```
orca quildjob.1.inp
```

and gives the corresponding quildjob.1.engrad file.

For the use with MOPAC the 2009 version of Mopac is needed (see http://openmopac.net) (http://openmopac.net), and SCM_MOPAC should be set to the location where MOPAC is installed. The first line of the MOPAC subblock should contain the AUX(0) directive, as in the following example:

```
DESCRIPTION 3 MOPAC
  AUX(0) BONDS CHARGE=0  SCFCRT=1.0D-8 PM3 1SCF GRAD
  Coordinates generated by AMSinput (c) SCM 1998-2008
SUBEND
```

Finally, note that the MOPAC subblock should contain 2 lines !

For the use of QUILD with a GENERIC program, the input is straightforward:

```
DESCRIPTION 3 GENERIC
  ! Here the specific input for the user-provided GENERIC program
SUBEND
```

It should be noted that by default, QUILD will use $AMSBIN/quild_generic as script for use with the GENERIC subblock (this example script facilitates the use of HONDO). However, this can be overridden by setting the environment variable $QUILD_GENERIC to a user-provided script (see also the *GENERIC* (page 35) description).

# INPUT DESCRIPTION

## 11.1 Relevant Keywords in QUILD block

| name | default | description |
| --- | --- | --- |
| CVG_ENR | 1.0e-5 | Convergence criterion for energy (when IDCVG $\geq$ 2) |
| CVG_GRD | 1.0e-4 | Convergence criterion for maximum component of gradient; depending on the value of IDELOCAL, either the delocalized or Cartesian gradient is checked |
| CVG_STP | 1.0e-4 | Convergence criterion for maximum component of step (when IDCVG $\geq$ 2) |
| DIFSTEP | 1.0e-5 | Stepsize for numerical differentiation (with numerical gradients/Hessian)) |
| I_ADD_DUMMI1 | 1 | Index to do (1) or do not (0) add dummy atoms for avoiding (nearly-)linear angles |
| ICREATE | 7 | Index which method to use for generating the primitive coordinates |
| IDCVG | 1 | Index how to signal convergence: |
| | | 1. check nr. of negative Hessian eigenvalues is correct and max. component and rms value of gradient are less than the convergence criterion (see CVG_GRD) |
| | | 3. same as 1, but both max. component of step and change in energy should be less than their respective convergence criteria (see CVG_STP and CVG_ENR) |
| | | 2. same as 3, but only of the additional criteria has to be fulfilled |
| IDELOCAL | 1 | Kind of coordinates to use in the geometry optimization: |
| | | 1. adapted delocalized coordinates |
| | | 0. Cartesian coordinates |
| IDIIS | 3 | Kind of GDIIS equations to use: |
| | | 0. original GDIIS |
| | | 1. same as 0, but with Farkas-Schlegel rules applied |
| | | 2. use gradient as error vector |
| | | 3. same as 2, but with Farkas-Schlegel rules applied |
| | | 4. use 'energy' vector as error vector |
| | | 5. same as 4, but with Farkas-Schlegel rules applied |
| IDSTEP | 5 | Step to take: |
| | | 1. RSO for minimizations, RFO (Baker) for TransitionStates |
| | | 3. RFO (Baker) always |
| | | 5. Generalized RSO (Swart) using image-function for TransitionStates |
| IEXCST | 1 | Number of excited state to use for numerical gradients By default for singlet excited state; triplet excited state can be used by adding ONLYTRIP keyword to EXCITATIONS block on input |
| IHOPT | 3 | Index for force constants method to use for initial Hessian: |

Table 11.1 – continued from previous page

| | | |
|---|---|---|
| | | 0. Baker (0.5 bonds, 0.2 angles, 0.1 dihedrals) |
| | | 1. Thomas Fischer |
| | | 2. simplification of Lindh |
| | | 3. Swart-Bickelhaupt scheme |
| | | 7. Swart generalized scheme (works well for close to minima) |
| IHUPD | -1 cq. 4 | Index for Hessian update scheme: |
| | | 1. BFGS for Hessian (-1 BFGS for inverse Hessian) |
| | | 2. Powell-symmetric-Broyden, PSB (for Transition States) |
| | | 3. Murtagh-Sargent (Symmetric Rank-One, SR1) |
| | | 4. Bofill weighted combi of PSB and SR1 (for Transition State) |
| | | 5. Farkas-Schlegel weighted combi of BFGS and SR1 |
| | | 6. Bakken-Halgaker combi of BFGS and SR1 |
| IQUILD_OUTPU | 1 | Amount of output requested, debug output $\geq 2$ |
| IRESTART | 0 | Index if ADF/ORCA jobs should restart from t21.files from previous geometry |
| | | < 0 ORCA uses restart, ADF not |
| | | > 0 both ORCA and ADF use restart |
| ITRUST | 0 | Index if dynamic trust radius should be used (1) or not (0) |
| MXDIIS | 5 | Maximum number of GDIIS vectors to use |
| MXGEO | 50 | Maximum number of geometry cycles (overrides value read from ITERATIONS in GE-OMETRY block) |
| NR_REGIONS | 1 | Number of different regions for multi-level approach |
| NRLT | 0 | Number of LinearTransit steps |
| RTRUST | 0.20 | Trust radius value |
| SMETAGGA | • | String for functional from METAGGA post-SCF scheme to use for numerical gradients, should be given exactly as on METAGGA output |
| TRUST_ALFA | 1.20 | Factor to increase trust radius with if $\Delta$ energy agrees with model prediction |
| TRUST_BETA | 0.70 | Factor to decrease trust radius with if $\Delta$ energy does not agree with model |
| TRUST_GOOD | 0.80 | Lower threshold for increasing trust radius |
| TRUST_RMIN | 0.40 | Upper threshold for increasing trust radius |

The other keywords that are printed in the output are for debug purposes, under development, or of technical nature. More information about them can be obtained (if needed) from SCM or M. Swart.

## 11.2 CONSTR subblock in QUILD block

Constraints can be supplied in the CONSTR subblock of QUILD. Below are the different option that are possible:

```
QUILD
  CONSTR
    dist   1 2        0.9
    angle  1 2 3    120.0
    dihed  1 2 3 4  100.0
    x      1          0.0   ! only with idelocal=0
    y      1          0.0   ! only with idelocal=0
    z      1          0.0   ! only with idelocal=0
  SUBEND
END
```

The units of these constraints are determined by the parameters in the UNITS block. The numbers in this subblock refer like usual to the atom numbers, as they are found in the ATOMS block.

A special case is observed for LinearTransit calculations, as given in the example below.

```
QUILD
  nrlt 11
  CONSTR
    dist   1 2         1.0    2.0
    angle  1 2 3     120.0   70.0
  SUBEND
END
```

Here there are two LinearTransit coordinates, i.e. the distance between atoms 1 and 2 and the angle 1-2-3. The distance between atoms 1 and 4 is a simple constraint throughout the whole calculation.

## 11.3 FROZEN subblock in QUILD block

Another way to introduce constraints is by freezing certain atoms. This can be achieved with the FROZEN subblock of QUILD, where either all three Cartesian (x, y, z) coordinates of an atom (or a series of atoms) can be frozen, or only one of the three:

```
QUILD
  FROZEN
     x     1-37   ! the X-coordinates of atoms 1 to 37 are kept frozen
     xyz  48-256  ! the X,Y,Z-coordinates of atoms 48 to 256 are kept frozen
  SUBEND
END
```

## 11.4 SYMROT subblock in QUILD block

Sometimes, one wants to lower the symmetry because of more convenient descriptions of d-orbitals of transition metals for instance. In that case, if one still wants to maintain the higher symmetry for the geometry, one can use the SYMROT subblock to rotate the coordinates. For instance, for $Fe(II)(Cl)_4^{2-}$ with $T_d$ geometric symmetry, the Fe d-orbitals are not conveniently separated. This might be better done within $C_{2v}$ symmetry:

```
Symmetry C(2v)

QUILD
 Symgeo T(d)
 Symrot
   -0.7071067811865475 -0.7071067811865475  0.0
   -0.7071067811865475  0.7071067811865475  0.0
    0.0                 0.0                  1.0
 Subend
End

Atoms

 CL           -1.876072079    0.000000000   -1.326583289
 CL            0.000000000   -1.876072079    1.326583289
End
```

The particular rotation matrix to be used depends on the choice made by the user for how to represent the molecule in the lower symmetry (see AMSinput how to impose symmetry).

## 11.5 TSRC subblock in QUILD block

The Transition State Reaction Coordinates that are used to construct the special initial Hessian, should be given in the TSRC subblock of QUILD. Similar to the CONSTR subblock, the distances, angles, or dihedrals should be specified, one per line, with atom numbers. The atom numbers should refer to the atoms as they are found in the ATOMS block.

```
QUILD
  TSRC
    dist   1 2
    angle  1 2 3
    dihed  1 2 3 4
  SUBEND
END
```

## 11.6 REGION subblocks in QUILD block

The definition of the different regions should be given in REGION subblocks of QUILD. Although the program counts the number of regions itself, it should be regarded good practice to make sure that the NR_REGIONS keyword corresponds to the correct number of REGION subblocks.

```
QUILD
  NR_REGIONS 2
  REGION 1
    1-11
  SUBEND
  REGION 2
    12 14 13 15 16 17 19 18 22 21 20
  SUBEND
END
```

The order in which the atom numbers are given does not matter, and in order that the input is easier to make and read, shortcuts are introduced. For instance, the "1-11" shortcut corresponds to "1 2 3 4 5 6 7 8 9 10 11" etc. Unlike other multi-level approaches, there is no need to have a shell structure for the different regions. I.e., the regions can overlap, or be defined as given above for DNA.

## 11.7 ADDREMOVE subblock in QUILD block

There is no ADDREMOVE subblock of QUILD active yet, but in the future it will be added to be able to control how the capping atoms will be added in the case of regions with dangling bonds. I.e., which elements should be added, and so on. For the moment, only hydrogens will be added, which works without problems for QM/QM and/or QM/MM calculations on DNA, or simple peptides. Future developments should decide whether this needs to be adapted.

## 11.8 DESCRIPTION subblocks in QUILD block

In case of multi-level jobs, where different regions are treated with different methodologies, the different methodologies should be given in the DESCRIPTION subblocks.

```
QUILD

  SUBEND
  DESCRIPTION 7 GENERIC NUMGRAD NUMFREQ
  ! input-description specific for GENERIC program
  ! for the system under study (see above)
  SUBEND
END
```

Description 1 here applies to OPBE/TZ2P(ae) with ADF, description 2 to B3LYP/DZ(ae) with ADF, description 3 to UHF/STO-3G through the ORCA interface, and finally descriptions 4 to 7 apply to description for NEWMM, DFTB, MOPAC and GENERIC respectively.

The input for multi-level approaches has been explained above. The standard input should be given for ADF, DFTB and NEWMM. See the corresponding User Manuals for ADF, DFTB and ADF-QM/MM respectively for them. Also for ORCA should standard input be used, the only exception being the total charge and multiplicity, which should be given as a partial %coords block. The QUILD program will then add the atomic coordinates to this block for the "black-box" inputfiles.

## 11.9 Numerical versus analytical Hessians for multi-level vibrational frequencies

The descriptions on the previous page indicate for some of the programs, whether the gradients and Hessians can be obtained analytically (no extra keywords necessary) or numerically. In the latter case, depending on if it is for the gradients or Hessian, one should add NUMGRAD or NUMFREQ to the DESCRIPTION line (see previous page). The QUILD program will then take care of preparing the correct number of jobs etc.

## 11.10 Use of a GENERIC description for use with user-provided QM-program

The 2009.01 version of QUILD allows the user to create his/her own script for use with a QM-program (e.g. HONDO, Molcas, etc.) for which no standard interface is available yet within QUILD. For this purpose (and with the GENERIC description above), the QUILD program writes a generalized inputfile for this script that consists of the following:

Line 1:

```
NAT IQRUN
NAT    number of atoms
IQRUN  type of job:
       0 single-point energy
       1 single-point energy+grad
       2 single-point energy+grad+Hess
```

Line 2 to NAT+1

```
ATOM X  Y  Z
ATOM   atomname
X      Cartesian X-coordinate (in Å)
Y      Cartesian Y-coordinate (in Å)
Z      Cartesian Z-coordinate (in Å)
```

Remaining lines

```
User provided lines on input (within DESCRIPTION block)
```

The user should then make sure that his/her script runs their program, and extract data from it in the following manner (the QUILD program reads these lines as free format, e.g. spaces or upper/lowercase are not important):

```
# ------------------------------------------------
# lines starting with # will be ignored by QUILD
# ------------------------------------------------
# ---------------
# number of atoms
# ---------------
[nat]    3
# ----------------------
# total energy (Hartree)

## 11.11 Spin-contamination correction per region

Previously, the spin-contamination correction was done for the complete system, but starting from version 2009.01 it can be performed for different regions, as in the following example:

```
QUILD
  DESCRIPTION 1 ADF
    Occupations smearq=0.0  &
      AA1          4.0     //      5.0
      AA2          0.0     //      0.0
      EE1          8.0     //      8.0
      EE2          6.0     //      4.0
    AAA1           0.0     //      0.0
    AAA2           4.0     //      4.0
    EEE1           6.0     //      6.0
    EEE2           4.0     //      4.0
    End
    CHARGE 0.0 1.0
    Unrestricted
  SUBEND

  DESCRIPTION 2 ADF
    Occupations smearq=0.0  &
      AA1          5.0     //      4.0
      AA2          0.0     //      0.0
      EE1          8.0     //      8.0
      EE2          6.0     //      4.0
    AAA1           0.0     //      0.0
    AAA2           4.0     //      4.0
    EEE1           6.0     //      6.0
    EEE2           4.0     //      4.0
    End
    CHARGE 0.0 3.0
    Unrestricted
  SUBEND

  INTERACTIONS
    TOTAL  description 1
    S2CORR region 1 spin-splus-description 2 for contaminated-description 1
  SUBEND

END
SYMMETRY D(5H)
```

Note that this in this case, the spin-contaminated system (doublet) consists of a triplet-alfa in the EE2-irrep coupled with a doublet-beta in the AA1-irrep. This is corrected for by a pure quartet, and the corresponding energies corrected:

```
Values for S2correction  1 :
s2cont        1.75396
s2pure        0.75000
s2plus        3.78716
a_s2          0.33056
jobsigns  job  2   -0.49378     job  1    1.49378
```

## 11.12 INTERACTIONS subblock in QUILD block

One of the most important input-parts for multi-level jobs is the INTERACTIONS subblock of QUILD, where one should define how the different descriptions should be applied to the different regions. At the part where we explained the multi-level approaches, we already showed some examples of how to combine different methodologies. Below is another example input where all possible options are given.

```
QUILD
  INTERACTIONS
    TOTAL      description 1
    REPLACE    region 1 region 2     description 3 for description 2
    REPLACE    region 1              description 4 for description 3
    INTXN      region 1 region 2     description 3 for description 2
    S2CORR     region 1  spin-splus-description 2 for contaminated-description 1
  SUBEND
END
```

If an INTERACTIONS subblock is present (if none is present it means no multi-level setup is done, i.e. pure QM or MM), there should always be a line with the description of the total system, as shown in the first line of the INTERACTIONS subblock. Then if you want to replace the interactions for one (or more) region(s), you could do so as indicated in the second and third line. Finally, if you want to replace the interaction between two regions, as we need for DNA where we replace the BP86 $\pi$-stacking by LDA $\pi$-stacking, the fourth line of the INTERACTIONS subblock should be used. Finally, the last line can be used for spin-contamination corrections for one (or more) regions.

Note that in all cases it is not necessary at all to add the "region", "description" and "for" words in the INTERACTIONS subblock; they are ignored when reading the input. The program reads the line, uses the last two integers for the descriptions and the ones before for the regions. Therefore, a completely equivalent input would be as shown below. However, for better readability, it is to be advised to always use the additional text anyway.

```
QUILD
  INTERACTIONS
    TOTAL            1
    REPLACE    1 2    3 2
    REPLACE    1      4 3
    INTXN      1 2    3 2
    S2CORR     1      2 1
    S2CORR     1 3    2 1
  SUBEND
END
```

Note that in the last line, it is indicated that the spin-contamination correction is applied to regions 1 and 3 together.

## 11.13 INLINE options in the QUILD block

Similar to the situation in ADF, one can use the INLINE directive to read specific input-lines from a file rather than from input. In general, this should make no difference, but in rare instances (for instance if the $ sign is needed in inputfiles for one of the programs), it might become useful.

# EXAMPLE INPUTFILES

A set with many more examples is provided in the $AMSHOME/examples/quild directory.

# REQUIRED CITATIONS

When you publish results in the scientific literature that were obtained with programs of the ADF package, you are required to include references to the program package with the appropriate release number, and a few key publications.

**For calculations with the Quild program**

M. Swart and F.M. Bickelhaupt, *QUILD: QUantum-regions interconnected by local descriptions*, Journal of Computational Chemistry 29, 724 (2008) (https://doi.org/10.1002/jcc.20834)

## 13.1 External programs and Libraries

Third party software used in the 2025.1 version of the Amsterdam Modeling Suite can be found in the file titled "third-party-software.txt" in the root of your AMS installation.
